

Elasticity

It is the property of the material to regain its original shape and dimensions, after the removal of external deforming force.

Perfectly elastic body — The body which completely regains its original shape after the removal of external deforming force.

Elastic limit — A certain limit below which if the deforming force is applied the body will regain its original dimensions but above the certain limit if deforming force is applied, body will get permanently deformed. This limit is called Elastic limit.

Stress — When external forces or deforming forces are applied on the body under equilibrium there is a relative displacement of its particles and results in internal forces of reaction which tends to oppose or balance the deforming forces within elastic limit, then body is said to be under stress.

Notes Stress = $\frac{\text{Force}}{\text{Area}} = \text{N/m}^2$.

Stress

↓

Tangential stress (shearing)
(When the stress is applied
along the surface)

19 tue results in the change of
shape of the body.

Normal stress
(When stress is applied
perpendicular to the
surface) ↓
results in change in
length or volume.

Strain — When body is under stress, it undergoes a change in length or volume or shape. This change in the dimension of the body to the original dimension or measured per unit dimension is called as strain.

20 wed

$$\text{Linear strain} = \frac{l - l_0}{l_0} - \text{change in length}$$

l — Original length.

$$\text{Volume strain} = \frac{V - V_0}{V_0} - \text{change in volume}$$

V — Original volume.

shearing strain = Angular deformation in the body
 θ

Notes

April

21 Thu

Hooke's law — Provided the ~~strain~~ strain is small, the stress is directly proportional to strain, within the elastic limit. or if the strain is small, ratio of stress to strain is constant within its elastic limit.

22 Fri

$E = \frac{\text{stress}}{\text{strain}}$ → Modulus of Elasticity or coefficient of elasticity. [E].

1) Young's Modulus $\gamma = \frac{\text{Linear stress}}{\text{Linear strain}} = \frac{F/A}{L/L}$

2) Bulk modulus $K = \frac{\text{Pressure}}{\text{Volume strain}} = \frac{F/A}{-V/V}$.

23 Sat

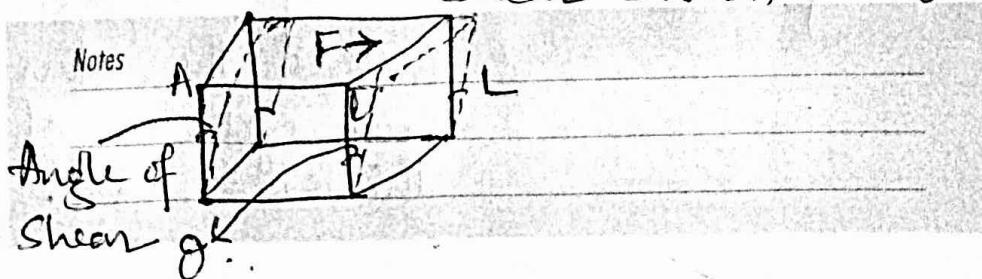

$K = \frac{-F/A}{V/V} = -PV$. Negative sign - if pressure increases, the volume decreases.

Incompressibility of the material of the body.

Bulk modulus is observed only in case of liquids and gases.

3) Modulus of Rigidity $\eta = \frac{\text{Tangential stress}}{\text{shear strain}} = \frac{F/B}{\theta}$.

2005

$$\text{Poisson's ratio } \sigma = \frac{\text{Lateral strain}}{\text{Linear strain}}$$

$$= \frac{\text{Secondary strain}}{\text{Primary strain}} = -\frac{\nu}{\epsilon}$$

Lateral strain — is the strain at right to the applied force.

Linear strain — is the strain in the direction of applied force.

Expression for couple for a unit twist or Torsion of a cylinder or Torsional rigidity of the material of wire

Consider a solid cylinder (wire) of length l and radius R to be fixed at its upper end. Let the couple (chuck nuts) be applied at its lower end such that it is twisted by θ . Now, naturally a resisting couple comes into action trying to oppose the twisting couple applied. and being the cylinder in equilibrium position.

In order to calculate the value of this couple, let us imagine the cylinder to consist of large number of co-axial cylinders, one inside the other and consider one such cylinder of radius ' x ' and thickness ' dx '.

April 2005

Notes

May

5th

Moment of Force = Force \times perpendicular distance from line of action (couple)

\therefore Moment of force = $F \times x$.
(About the axis)

6th
Couple = $\frac{2\pi \eta \theta}{l} \cdot x^3 dx \rightarrow \textcircled{1}$ This is for only one layer of coaxial cylinder.

For the complete / whole cylinder, Integrate couple between $x=0$ to $x=R$.

\therefore The twisting couple for the entire cylinder is

$$= \int_0^R \frac{2\pi \eta \theta}{l} \cdot x^3 dx \quad \text{or} \quad \frac{2\pi \eta \theta}{l} \left[\frac{x^4}{4} \right]_0^R$$

$$= \frac{2\pi \eta \theta}{l} \cdot \frac{R^4}{4} \Rightarrow \frac{\pi \eta R^4}{2l} \cdot \theta$$

\therefore Twisting couple = $\frac{\pi \eta R^4}{2l} \cdot \theta$

| 19 | 20 | 21 | 22 | 23 | 24 | 25 |
| 26 | 27 | 28 | 29 | 30 | | |

Notes

May

9 mon

2005

In the above expression, If $\theta = 1$,

$$\text{Twisting couple} = \frac{\pi \eta R^4}{2l}$$

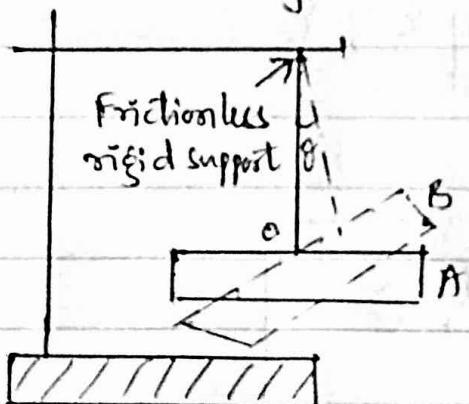

$\therefore C = \frac{\pi \eta R^4}{2l}$ → Torsional rigidity of the material of wire.

10 tue

Since, twisting couple is analogous to restoring couple, so twisting couple can also be called as restoring couple per unit twist.

Torsional Pendulum -

Any rigid body, capable of executing angular simple harmonic motion in horizontal plane about the vertical axis passing through centre of the gravity of the body is called as torsional pendulum.

Consider a torsional pendulum in any forms, here as a rectangular bar, suspended by a wire. One end of the wire is fixed to a rigid and frictionless support. And

other end is attached to centre of mass of solid, here 'O' is the centre of bar.

| 24 | 25 | 26 | 27 | 28 | 29 | 30 |

May

2005

12 thu

When the bar is twisted from A to B, then the wire is also twisted by same angle and restoring torque is produced in wire, which tends to bring the wire in the equilibrium position. So, the restoring torque or twisting torque acting on the wire is $\Rightarrow C\theta$.

13 fri

$$= \frac{\pi \eta R^4}{2l} \cdot \theta$$

$$\therefore C = \frac{\pi \eta R^4}{2l} \rightarrow \text{torsional rigidity of the material of wire.} \rightarrow ①$$

Now, If 'I' moment of inertia of the rectangular bar, about the axis of the wire, passing through its centre, 15 sun

$$\frac{d^2\theta}{dt^2} = \text{Angular acceleration,}$$

$$I \cdot \frac{d^2\theta}{dt^2} = \text{couple acting on rectangular bar} \rightarrow ②$$

Eqn ① and ② implies couple acting on the bar and wire.

$$\therefore I \frac{d^2\theta}{dt^2} = -C\theta$$

\Rightarrow Negative sign indicates that restoring couple is oppositely directed to angular displacement θ

Beam A rod or bar of a circular or rectangular cross-section with its length very much greater than its thickness (so that no shearing stresses over any section of it) is called a beam.

Bending of a Beam —

Consider a beam of rectangular cross section fixed at one end and loaded at other end.

ABCD is the beam fixed from AD end and free from BC end and 'W' load is suspended at free end.

- Due to moment of load 'W' it will bend down.
- AB portion of beam will increase in length due to tension or tensile stress acting outward.

- CD portion of beam will get compressed due to compressing stress acting forward.

2005

Neutral axis - It is the axis of the beam in which ~~length~~ neither get extended nor get compressed ie retain original length.

Bending Moment - ABCD is a beam.

- a) Due to moment of 'W' the beam will get bend in downward direction. The ~~and~~ equal and opposite force acts in upward direction along EF \uparrow . Both these forces constitute a couple called as bending couple which will bend beam in clockwise direction and its moment is called as bending moment.
- b) Since beam is in equilibrium, another couple comes into action, which causes beam to resist the bending or will balance the beam.
- This couple is called balancing couple. This arises due to the compressive stress acting on 'DC' portion and tensile stress acting on 'AB' portion of the bar or due to forces acting above and below neutral axis NN'
